Docker Assignment 1: Ubuntu Container with vim, git and tree

Oct 8, 2026

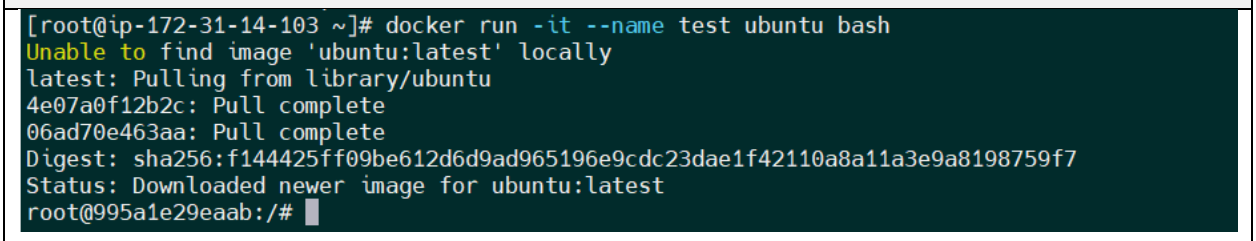

Create an Ubuntu container, install vim, git and tree inside it, and paste a screenshot under each step as proof. The Ubuntu image is minimal, so `apt update` must come before any install.

Step 1: Create and enter the container

Run on the EC2 host; this creates a container named `test` and logs you into it.

```
docker run -it --name test ubuntu bash
```

Screenshot 1: container created, prompt shows root@

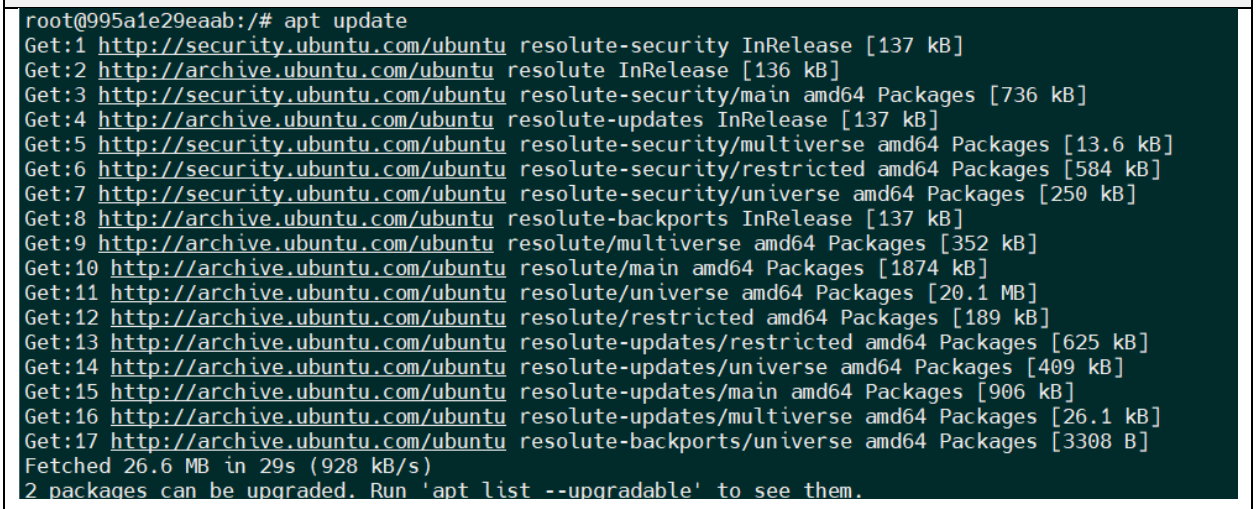

Step 2: Update the package lists

Run inside the container. You are root, so no sudo is needed.

```
apt update
```

Screenshot 2: apt update output

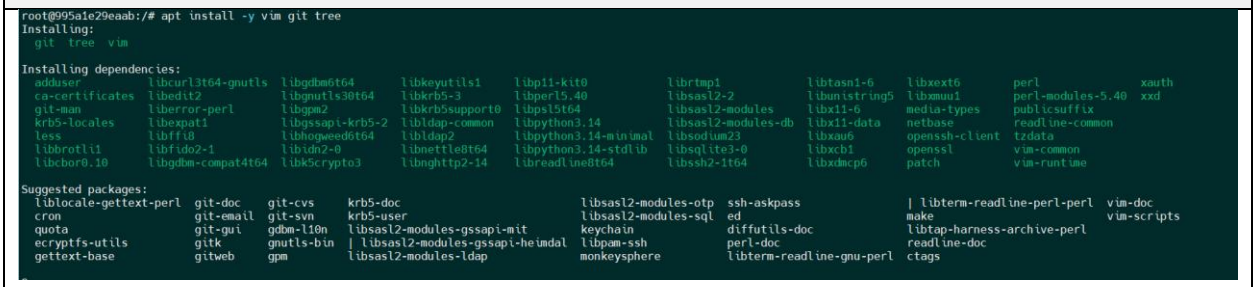

Step 3: Install vim, git and tree

```
apt install -y vim git tree
```

Screenshot 3: installation output

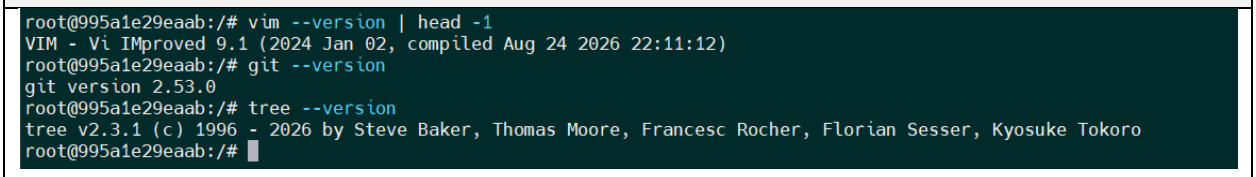

Screenshot 3: installation output

Step 4: Verify the tools

```
vim --version | head -1
git --version
tree --version
```

Screenshot 4: three version outputs

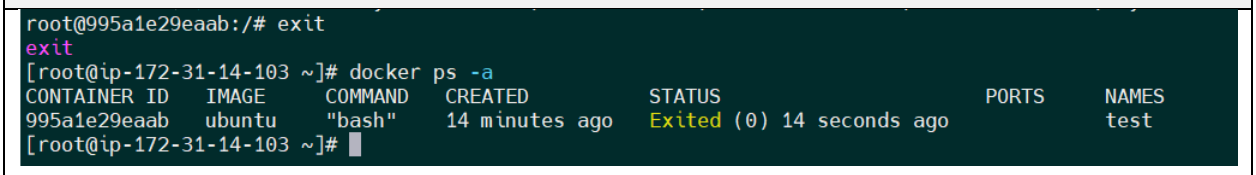

Step 5: Exit and check the container

`exit` ends bash, which is PID 1, so the container stops. Then run `docker ps -a` on the host to see it with status Exited.

```
exit
docker ps -a
```

Screenshot 5: docker ps -a showing test as Exited

Optional: come back later

To return with the tools still installed, run `docker start -ai test`. Removing the container with `docker rm test` deletes the tools with it; to keep them, run `docker commit test ubuntu-tools`.
